Annex 10.1.4	Peat Depth Model Methodology

## 1 Introduction

- 1.1.1 In support of **Chapter 10 (Volume 1)** of the Design Manual for Roads and Bridges (DMRB) Stage 3 Environmental Impact Assessment (EIA) report; this technical appendix describes the nature and findings of peat survey work undertaken for Project 9 – Crubemore to Kincraig of the A9 Dualling Programme (hereafter referred to as the Proposed Scheme). It describes the importance of peatland, its functions, values and general characteristics, followed by the scope, method and findings of field surveys completed for the Proposed Scheme.
- 1.1.2 The information available and presented herein, supports the potential impacts assessed within **Chapter 10 (Volume 1)**, the preliminary peat landslide risk assessment analysis in **Appendix 10.5 (Volume 2)** and the Outline Peat Management Plan (OPMP) in **Appendix 10.6 (Volume 2)**. These and other relevant aspects of the DMRB Stage 3 EIA should therefore be referred to as necessary.

## 2 Background and Definitions

### 2.1 Definition of Peat

- 2.1.1 In Scotland, peat is defined as “*an organic soil which contains more than 60 per cent of organic matter and exceeds 50cm in thickness*” (Macaulay Institute, 1984). Scotland’s National Peatland Plan also encompasses organic soil less than 50cm, which can support typical peatland vegetation (SNH, 2015a). Organic deposits less than 50cm in thickness are therefore considered in this Appendix and related aspects of the DMRB Stage 3 EIA as ‘peaty soils’. The Joint Nature Conservation Committee (JNCC) (2011) and Scottish Government (2014) guidance on peat surveys also follow this peaty soil definition. ‘Deep peat’ is considered to be a peat soil with a surface organic layer greater than 1.00m thickness (Bruneau and Johnson, 2014).
- 2.1.2 The structure of an active peatland typically comprises a thin surface layer of living vegetation (the *acrotelm*) overlying a usually thicker layer of well decayed and humified peat, comprising the consolidated remains of former surface vegetation (the *catotelm*). Below the peat forming layers is the basal *substrate*, either a mineral soil, mineral superficial deposit or bedrock.
- 2.1.3 The acrotelm is the upper aerobic layer of peat and consists of living and partially decayed plant material. It typically has a higher hydraulic conductivity than underlying peat and is usually defined in relation to the water table. Acrotelm thickness varies with topography – such as hummocks, peat hags, hollows and with time, especially in dry periods or when it is drained.
- 2.1.4 The catotelm layer sits beneath the acrotelm and consists of well decayed and humified material, and is denser with a very low hydraulic conductivity. Conditions are anaerobic and anoxic because the catotelm is permanently below the water table.

### 2.2 Peatland Importance

- 2.2.1 Over 20% of Scotland’s land area is covered by peatlands, and Scotland hosts a significant proportion of the European and world resource. Foremost, peatlands are long-term carbon stores, important to tackling climate change; but they are also important to rural farming, tourism, in providing clean water and in lowering flood risks. Scotland’s National Peatland Plan published by Scottish Natural Heritage (SNH) also notes that they form beautiful landscapes, represent key habitats and are a defining characteristic of wild Scotland (SNH, 2015a).
- 2.2.2 Drying and physical damage to peat can release greenhouse gases, reduce water quality and diminish a range of other services. Peat is also geotechnically complex, and special consideration

must be given to the practicalities of engineering in peat and peat soils, with careful management of construction activities required to avoid such damage.

## 2.3 Peatland Habitats and Vegetation

2.3.1 The internationally recognised term for a peat forming system is a *mire*. However, important peat deposits can be present where peat is not actively forming and therefore, peatland is a more appropriate term to consider in this context. A definition of peatland, modified from the Ramsar Convention of 1971 is “*land with a peat deposit that may currently support a vegetation that is peat forming, may not, or may lack vegetation entirely*” (IUCN, 2014).

2.3.2 Peatland types can be defined in different ways; according to vegetation, soil or geology. However, Scotland’s National Peat Management Plan (SNH, 2015) and peat bog ecosystem guidance by IUCN (2014) provide useful, similar differentiations between broad types of natural peatland, which consider a range of factors. The four main natural types include:

- **Blanket bog:** found in few parts of the world with cool, wet and typically oceanic climates. Under these conditions, bog mosses and other plants break down very slowly and gradually to form a layer of peat. Peat depth varies, but is usually between 0.50 and 3.00m deep, and with depths of up to 8.00m not uncommon. The source of water for these is directly from rainfall.
- **Raised bog:** mainly found in lowlands, these bogs appear as domes growing up to 10.00m or more in height. As with blanket bog, the source of water for these is directly from rainfall.
- **Fen:** usually low, marshy wetlands where groundwater, enriched by the chemistry of mineral soils, causes waterlogging. In upland environments, this habitat type includes valley mires, which can transition to blanket bog on valley sides.
- **Bog woodland:** similar to the open peatlands described above, but supports tree species such as Scots pine, birch and willow.

2.3.3 All peatlands in the UK have developed under peat-forming vegetation, but a wide range of other vegetation types can also occur over peatlands as a result of land management. Many of these can represent habitats or include vegetation species of conservation importance, including those listed in Annex 1 of the European Council Habitats Directive 92/43/EEC (Council of the European Communities, 1992), identified as UK Biodiversity Action Plan priority habitats or vegetation, or identified on the Scottish Biodiversity List (SBL) (Scottish Government, 2013).

2.3.4 Several vegetation types are associated with wet conditions conducive to peat formation within peatland habitats, and represent their most active and least damaged state. Based on Bruneau and Johnson (2014), these may include:

- **Bog vegetation:** National Vegetation Classification (NVC) communities M17 to M20 define the core range of blanket bog and raised bog vegetation in the UK, with the representation of bog-pool communities M1 to M3 varying in relation to climate and land management.
- **Fen vegetation:** in nutrient rich fen, vegetation may include M9, M10, M13, M14 and S24; with these developing at locations subject to the influence of calcareous, but nutrient-poor water. Nutrient-poor, acidic water promotes bog-like **poor fen** vegetation including M4 to M8 and M21 vegetation of bog mosses, sedges, cotton-grass and dwarf shrubs. Many examples of poor fen also occur as soligenous features (flushes and springs), often in association with bog or marshy grassland vegetation.
- **Purple moor-grass:** M25 is a deciduous grass and a natural component of bog and poor fen vegetation. Under certain drainage and burning management, such peatlands can become

almost completely dominated by this species, thus representing degraded or modified bog. The annual build-up of purple moor-grass litter can form peat, especially where it accumulates in pools. However, the extent to which purple moor-grass dominated vegetation is important in on-going peat formation is not known.

- **Wet heath vegetation:** NVC communities M15 and M16 cross-leaved heath, deer-grass and bog moss are most widespread on shallow peaty soils, but can also occur on deeper peats influenced by drainage, burning or cutting.

2.3.5 Other types of semi-natural vegetation not associated with the formation of waterlogged peat can also occur over peaty soils as a result of management and environmental impacts. On blanket bogs and shallow peatlands for example, drainage, rotational burning, grazing and air pollution can be responsible for the development of **dry heath** vegetation (H8 to H10 and H12). This is however most usually associated with the formation of thinner organic or peaty soils in freely draining areas and is unlikely to form deep peat under the current climate.

## 2.4 Condition and Function of Peatland

2.4.1 Peatland characterisation has traditionally focused on vegetation, hydrological or developmental criteria, but they can also be described according to their degree of degradation, condition and function, as summarised in **Table 1** (after Bruneau and Johnson, 2014).

Table 1: Categories and Condition of Peatland

<b>Peat Category</b>	<b>Structure, Vegetation and Management</b>	<b>Water table</b>	<b>Organic matter dynamics</b>
<b>Active</b> 	Semi-natural vegetation cover of bog mosses, cotton grasses and dwarf shrubs (bogs, poor-fens) and medium-tall graminoids, forbs and hypnoid mosses (other fens). Might include Purple moor-grass dominated vegetation in some circumstances. Diplotelmic structure in case of bogs and some fens, with true acrotelm of living bog mosses and/or recently deposited plant litter Sympathetically managed and restored mires.	Water table mostly fluctuates within acrotelm rooting zone. Catotelm /deeper peat remains more or less permanently waterlogged.	Organic matter fixed and starts to degrade in acrotelm, releasing some CO <sub>2</sub> New peat material enters long-term storage at top of catotelm – little CO <sub>2</sub> released, slow release of CH <sub>4</sub> . Acrotelm may oxidise some CH <sub>4</sub> into CO <sub>2</sub> . Optimal state for long-term storage of carbon in catotelm
<b>Degraded</b> 	Semi-natural vegetation, but with balance of graminoids/forbs/ericoids and bryophytes changed by adverse/lack of management. Acrotelm absent or impacted. Could include forestry if some bog flora remains. Associated with burning, drainage, afforestation of peatland.	Water table fluctuates within previously accumulated catotelm peat. Taller vegetation draws water from peat surface layers.	Falling litter degrades at peat surface, or in upper peat layers. Little new organic matter reaches area of permanent waterlogging. Upper catotelm peat degrades into CO <sub>2</sub> and becomes more decomposed (humified). More CH <sub>4</sub> is oxidised in upper peat layers. Can be subject to peat shrinkage.
<b>Bare</b> 	No true acrotelm. No vegetation. Associated with peat cutting, wildfire, pollution, overstocking or cultivation of peatlands. Some erosion complexes are long-standing and apparently natural.	Water table fluctuates within previously accumulated catotelm peat. Upstanding dry hags alternate with lower wetter but periodically dehydrated peat.	No new litter entering system. Catotelm peat degrades into CO <sub>2</sub> but extremes of temperature probably retard degradation. CH <sub>4</sub> emissions may increase – mechanism unknown. Much peat lost through erosion by wind and water.
<b>Archaic</b> 	No true acrotelm Agricultural vegetation (grassland/ cropland) including cultivated land Forestry where no bog flora remains. Usually deep drained.	Water table controlled by ditch system, often with under-drainage Held typically at ~40-80cm below peat surface in catotelm May be brought closer to surface during winter in grasslands.	Plant litter degrades at peat surface or in upper layers. Upper catotelm peat degrades into CO <sub>2</sub> and becomes more decomposed (humified). Cultivation of soil increases oxidation of organic matter releasing more CO <sub>2</sub> . Little CH <sub>4</sub> released – dry surface peat may oxidise atmospheric CH <sub>4</sub> . Peat surface rapidly lowers due to decomposition and erosion of peat.
<b>Wasted or Lost</b> 	No true acrotelm or catotelm. Most peat has been lost or removed. Agricultural vegetation (grassland/cropland).	Water table mainly fluctuates within underlying mineral soils.	Peat organic matter increasingly mixed with soil mineral material. Some peat material stabilised. Decomposition of organic matter slows releasing less CO <sub>2</sub> . Little CH <sub>4</sub> released and some atmospheric CH <sub>4</sub> oxidised.

- 2.4.2 Bruneau and Johnson (2014) also clarify that all intermediate stages between active and bare peat are degraded. In such instances, the peat retains a semi-natural vegetation cover but is dominated by graminoid (grassy) or ericoid (heather-like) vegetation. Furthermore, the presence of erosion features such as gullies and peat hags can also result in mixtures of degraded and bare peat within a wider peatland environment.
- 2.4.3 SNH (2016) present a series of sub-categories, specifically aimed to allow the description of the degree of degradation in blanket bog, including:
- **Near natural condition:** sphagnum dominated, no known fires (either prescribed or wild) within living memory, evidence of grazing and trampling is rare or absent, little or no bare peat surface is present and heather (*Calluna vulgaris*) is not dominant.
  - **Modified:** bare peat in small patches, fires or fire history, frequent impacts of grazing and trampling, sphagnum mosses rare or absent, extensive cover of heather (*Calluna vulgaris*) or purple moor-grass (*Molinia caerulea*), an undesirable level of scrub drying out the bog.
  - **Drained:** within 30m of either an artificial drain (grip) or re-vegetated hagg/gully system.
  - **Actively eroding:** actively eroding hagg/gully system (most of their length having no vegetation in gully bottoms with steep, bare peat ‘cliffs’), extensive continuous bare peat surfaces (peat ‘pans’), extensive bare peat surfaces at former peat cutting sites, restoration may require a period of livestock removal and exclusion of wild herbivores.
- 2.4.4 According to the ‘*Wise Use of Mires and Peatlands*’ (Clarke and Joosten, 2002), there are several functions and values of peatlands that also make them valuable ecosystems. Although definitions of functions or values vary according to individual perception and interest, some of them are widely recognized as core ecosystem services. Based on the UK National Ecosystem Assessment (UK NEA) in this respect, the recognised services can be sub-divided by different types of peat-based habitats, as detailed in **Table 2** (UK NEA, 2011; JNCC, 2011) and where values range from negligible (-) to high (+++) importance.

Table 2: Ecosystem Services (Functions and Values) of Peatland

	Bracken	Dwarf shrub heath	Upland fen, marsh, swamp	Bogs	Montane	Fens	Grazing marsh	Lowland raised bogs	Headwater wetlands	Wet woodlands	Native pine wood
Likely soil associated	Shallow peat Mineral	Shallow peat Mineral	Deep peat	Deep peat	Shallow peat Mineral	Deep peat	Shallow peat	Deep peat	Mix	Shallow / deep peat	Shallow peat

## 2.5 Peatland Geomorphology

- 2.5.1 The geomorphology of peatlands varies depending on the nature of the peatland and the scale at which the geomorphological features are considered. Evans and Warburton (2007) categorise these features by scale.
- 2.5.2 At the large end of this scale are ‘macrotopes’ which are roughly synonymous to blanket bog, raised bog and fen. Morphologically at this scale, blanket bog is a mosaic of peat environments which ‘blankets’ uplands with peat and is comprised of a series of smaller components. Raised bogs and fen being domed bodies of peat and low-lying marshy peatland respectively, are both also comprised of smaller components.
- 2.5.3 At the next level down, Evans and Warburton (2007) describe a series of ‘mesotopes’ within blanket bog complexes comprising watershed mires, spur mires, saddle mires, valley side mires and ladder fens. Some of these may formerly have been distinctly separate morphological units, but over time have been incorporated into the overall bog complex as peat has accumulated. SNH (2015b) divide raised bogs at a similar scale, detailing three specific areas of a raised bog; the central, extensive, raised and rather level *mire expanse* and a *rand* of deep peat which slopes towards the *lagg*, which is the outermost lowest zone and only has a thin patchy peat cover so there is some nutrient enrichment from the underlying mineral soils. Equivalent sub-divisions at this scale in lowland fens are principally vegetation based (SNH, 2015c), but swamps and valley mire are specific sub-divisions likely to be found at this mesotope level.
- 2.5.4 At the smallest scale, Evans and Warburton (2007) describe a series of ‘microforms’. They describe several ‘hydro-ecological’ microforms present in blanket bogs including hummocks, ridges (high or low), hollows (sphagnum or mud-bottomed) and pools (permanent or ephemeral). IPCC (2016) describe a series of equivalent ‘ecotopes’ for raised bogs which include hummocks, flats, lawns, hollows and pools. In addition to these hydro-ecological microforms, Evans and Warburton (2007) also describe a series of geomorphological forms commonly found in blanket bog which include erosion gullies, erosion hags and peat mounds.
- 2.5.5 The geomorphological features described above are generally those found naturally in peatlands. However, artificial features can also be present and affect the geomorphology and function of peatland, particularly artificial drainage and scars from peat cutting and mineral extraction.

## 3 Approach and Methods

### 3.1 Scope and Guidance

- 3.1.1 Baseline conditions in relation to peat for the Proposed Scheme have been determined through desk-based data assessments, ground investigations (GI), dedicated walkovers and field surveys, as summarised in **Chapter 10 (Volume 1)**; with the level of information being progressive and reflective of the DMRB assessment stage and design development process described in **Chapter 4 (Volume 1)**.
- 3.1.2 Each aspect of the assessment and surveys completed have been undertaken in accordance with guidance provided in ‘*Developments on Peatland: Site Surveys*’ (Scottish Government *et al.*, 2014), ‘*Peat Depth Survey Guidance*’ (SNH, 2015d), ‘*Peatland Condition Assessment*’ (SNH, 2016), ‘*Peat Landslide Hazard and Risk Assessments: Best Practice Guide for Proposed Electricity Generation Developments*’ (Scottish Government, 2017) and ‘*Guidance on Developments on Peatland: Peatland Survey*’ (Scottish Government, SNH and SEPA, 2017).

### 3.2 Baseline Data

3.2.1 Several peat probing, sampling and walkover surveys and phases of GI have been undertaken prior to or in support of the DMRB Stage 3 EIA. The scope of work for these and data available for consideration in the assessment is summarised below:

- **Advanced Ground Investigation (Raeburn Drilling and Geotechnical Ltd (Raeburn), September to December 2015):** comprising 62 (no.) trial pits and 37 (no.) boreholes across and adjacent to the Proposed Scheme, with 24 (no.) basic peat and/ or von Post (Hobbs, 1986) peat and substrate descriptions, where encountered.
- A total of 126 (no.) peat depth probe measurements were also advanced throughout the study area, targeting areas of peat highlighted by British Geological Survey (BGS) mapping, though no descriptions of peat or substrates were obtained.
- **DMRB Stage 3 Peat Survey (CH2M Fairhurst Joint Venture (CFJV), February to March 2017):** comprising a total of 730 (no.) peat depth probe measurements across and adjacent to the Proposed Scheme.
- **DMRB Stage 3 Supplementary Peat Survey (CFJV, June 2017):** comprising a total of 153 (no.) peat depth probe measurements across and adjacent to the Proposed Scheme, focusing on areas with little/ no coverage from the previous survey. Core samples were recovered from 26 (no.) locations to obtain basic, von Post (Hobbs, 1986) and Troels-Smith (Norbury, 2016) descriptions of peat and substrate, where encountered.
- **Preliminary Ground Investigation (BAM Ritches, November 2017 to January 2018):** a total of 1,586 (no.) peat depth probe measurements were completed across and adjacent to the Proposed Scheme footprint. Core samples were recovered from 36 (no.) locations to obtain basic peat/ peaty soil and/ or von Post (Hobbs, 1986) descriptions of peat and substrate, where encountered.

Additionally, 194 (no.) trial pits and 148 (no.) boreholes were advanced across and adjacent to the Proposed Scheme, with 64 (no.) basic peat/ peaty soil and/ or von Post (Hobbs, 1986) peat and substrate descriptions obtained, where encountered. Laboratory testing of peaty soil and peat samples for all or a selection of nutrients, loss on ignition, moisture content, bulk density, pH, total carbon and total organic carbon from selected locations.

3.2.2 Dedicated site walkovers were undertaken to assess peatland areas (CFJV, March and November 2017) and to understand morphology and stability features. This was additionally supported and guided by Phase 1 Habitat (CH2M, 2014) and NVC Survey (MacArthur Green, 2015) findings.

3.2.3 Photographs obtained during the site walkovers are presented in **Annex 10.1.1** and their geo-referenced locations are shown in **Drawings 10.1.1 to 10.1.6 (Volume 3)**. All available depth and characteristic data is also attached in **Annex 10.1.2** and **Annex 10.1.3**, while Phase 1 Habitat and NVC Survey findings are described in **Appendix 12.2** and **12.3 (Volume 2)**, respectively.

### 3.3 Field Methods

3.3.1 For each relevant stage of the surveys and GI, the investigative works were targeted to specific Proposed Scheme elements and to gain an understanding of peat depth and characteristics across the study area. The following principles and methods were applied to the peat probing and sampling aspects of these:

- Survey areas and extents were identified and informed by published BGS and soil mapping, previous probing or GI information available at that time, and inferences of potential peat presence based on Phase 1 Habitat and NVC Surveys
- Peat probe depth measurements were taken using a 1.20m Van Walt Utility or Mackintosh Peat Probes with extensions, at least once every 100m across the Proposed Scheme, equivalent to a low resolution first pass (Scottish Government, 2014). Where peat and elements of the Proposed Scheme were expected to coincide, a more resolute density of measurements was applied
- Peat probe depth measurements were undertaken to refusal and full depth at all locations and, in the case of core samples, until substrate was evident in the core, if possible
- Core samples were retrieved across the full peat or peaty soil profile penetrable by hand, using either a 30mm diameter and 1.00m length gouge auger or Russian Corer for logging and/ or laboratory testing
- Core samples retrieved were targeted to the range of peat-based habitats and environments present (within and adjacent to the infrastructure footprint) and were described using the von Post (after Hobbs, 1986) and/ or Troels-Smith (Norbury, 2016) classification schemes
- At each core location, descriptions of the peat/ soil using the classification schemes were obtained at 0.50m intervals across the full profile recovered – including the uppermost peat/ sediments, nature of the substrate, depth to groundwater and details of the depth below ground level of the contact between the acrotelm and catotelm, if identifiable
- Sample descriptions have been retrieved at a combined total of 150 (no.) locations, equivalent to approximately 5% of all depth measurements available – which is in accordance with the minimum recommendations provided in '*Developments on Peatland: Site Surveys*' (Scottish Government, 2014) and '*Guidance on Developments on Peatland: Peatland Survey*' (Scottish Government, SNH and SEPA, 2017).
- Survey locations were recorded using a hand-held GPS (probe and core sample locations) or GPS Total Station (trial pit and borehole locations) and photographs were obtained at each core location to provide context. Where hand-held GPS failed or signals were weak, standard navigation techniques were employed to establish measurement point locations.

### 3.4 Peat Depth Model

- 3.4.1 All available data has been used to generate a detailed map of peat and peaty soil depth for the Proposed Scheme. This was created using ArcGIS 10.3.1 geographical information system software as described in **Annex 10.1.4**. The resultant model is shown in **Drawings 10.11 to 10.22 (Volume 3)**, together with the positions of the various probe, core, trial pit and borehole locations that have been advanced and that are available for consideration.

## 4 Peat Conditions

### 4.1 Published Mapping

- 4.1.1 As summarised in **Chapter 10 (Volume 1)** and shown in **Drawing 10.1 (Volume 3)**, BGS mapping identifies scattered areas of peat throughout the study area. The majority of these are located south and east of the existing A9 starting at ch. 40,000 and continuing to ch. 44,000, along with two smaller areas lying to the north near Ralibeg. The remaining areas are located north and west of Kingussie, between ch. 50,200 and ch. 56,645, with the largest of these lying directly

south of the existing A9 between ch. 51,600 and ch. 52,200. Published soil mapping (JHI, 2013) shown in **Drawings 10.4 and 10.5 (Volume 3)** also identifies areas of peaty soils, including peaty gleys, peaty podzols, peaty gleyed podzols and peaty alluvial soils.

- 4.1.2 SNH Carbon and Peatland mapping shown in **Drawing 10.6 (Volume 3)** shows that there are no areas of priority peatland (nationally important carbon-rich, peaty soils and deep peat present) within the study area, with it almost exclusively comprising Class 0 (mineral soils where peatland habitats are not typically found).

## 4.2 Geomorphology

- 4.2.1 The study area is situated within Badenoch landscape character area (SNH, 1996), with the southern extents predominantly located to the south of the River Spey on the river terraces and sloping ground which ultimately lead to the Cairngorm Massif. The study area then crosses the flat open Strath floor and the River Spey itself. North of the River Spey, the study area covers the very lowest parts of the gently undulating hills which lead up to Monadhliath Mountains.
- 4.2.2 Much of the flat-lying floor of the Strath Spey valley is occupied by extensive marsh and wetlands of northern fen. The predominant influences on the landscape have been glaciation and subsequent deglaciation during the Pleistocene, with powerful flows of ice over 700m thick across the study area, directed along Strath Spey from Rannoch Moor (Young, 1978; Hall *et al.*, 2016). Glaciation, deglaciation and associated processes have therefore created many of the landforms, as there is little to no observable geological control on either the topography or the drainage systems (Young, 1978). The predominant controls on the current landscape appearance are either erosion, deposition or subsequent erosion and reworking of glacial deposits by glacial movement and melt before circa 13,000 years ago; evidenced by the presence of glaciogenic features such as dead ice topography and kettle holes, and glaciofluvial features such as outwash fans (Sissons and Walker, 1974; Young, 1978).
- 4.2.3 As shown in **Drawing 10.1 (Volume 3)**, published BGS mapping indicates that the study area is predominantly comprised of widespread alluvial deposits and less widespread peat in the valley bottom, above which river terrace deposits (floodplain abandoned as the river has cut down) and glaciofluvial deposits in some areas are often found. Alluvial fans are also present at the outflow of larger tributaries to the River Spey, including the River Calder, Gynack Burn, Allt Cealgach and Raiths Burn. A substantial alluvial fan also exists between Gynack Burn and Allt Cealgach on an unnamed watercourse. The formation of these fans again relates to a glacial control, as a result of large volumes of meltwater containing great sediment loads draining directly towards the current course of the River Spey along meltwater channels. Some of these meltwater channels, as indicated, are presently streamless (Young, 1978) or contain streams too small to have formed the alluvial fans through which they flow. The hillslopes further from the existing A9 in the study area are mantled with diamicton till, with peaty soils and some areas of peat. Bedrock is generally reached at shallow depths except in some locations on the strath floor (Young, 1978).
- 4.2.4 Based on the geology and wider geomorphological context (Evans and Warburton, 2007), the study area provides two principal environments ('macrotopes') in which discontinuous mosaics of peat-forming areas exist; flatter flood plains and terraces (where local areas of peatland are low lying and marshy, most comparable to low-lying fens, floodplain and transition mire) and hillslopes (where areas of peatland are most comparable to upland blanket peat).
- 4.2.5 Peat cover deeper than 0.50m is discontinuous in these mosaic environments and smaller-scale morphological ('mesotope' and 'microtope') features are therefore sporadic. However, some are evident within and to the south and east of the study area; including flushes and hummocks on

sloping ground, and some localised hollows and bog pools around Newtonmore, Nuide, south of Kingussie and across the Insh Marshes.

- 4.2.6 No peat gullies or pipes have been identified and the otherwise lack of these smaller-scale hydro-ecological features is likely to be a result of anthropogenic impacts over time throughout the study area via muirburn, grazing, drainage, agricultural land use and woodland.

### 4.3 Habitats and Vegetation

- 4.3.1 Based on Phase 1 Habitat and NVC Surveys, peatland habitats and peat-forming or successional vegetation types have been identified locally in the study area. These include mire, blanket mire, wet heaths or mosaics of these and others, with some of the typical and indicative core vegetation ranges (Bruneau and Johnson, 2014) of **blanket bog** (M17, M19 and M1 to M3), **wet heaths** (M15 and M16), **degraded bog** (M25), **fens and flushes** (M4, M5, M6 and M10) and **wet woodland** (W3, W4, W6 and W7) represented. Semi-natural vegetation not associated with waterlogged peat formation, but that can occur over thinner organic and peaty soils on shallow peatlands includes **dry heath** (H10 and H12), **acid grasslands** (U2 and U4 to U6), **semi-natural grasslands** (MG9 and MG10), **bracken** (U20) and **scrub** (W23).
- 4.3.2 The distribution of habitats and vegetation types within the study area is shown in **Drawings 12.8 to 12.27 (Volume 3)** and described within **Chapter 12 (Volume 1)**. In summary and approximately however, those which are indicative of blanket bog account for 2% in total, with wet heaths (including areas in mosaic with blanket bog) accounting for 4%, dry heath around 17%, grasslands approximately 33%, and fens, flushes and swamp around 6%. Most of the vegetation appears to have been impacted anthropogenically over time. However, some areas of wet heath, blanket bog, other mires, fen, marsh and swamp located within and adjacent to the Proposed Scheme at Newtonmore, Nuide and across the Insh Marshes also appear sufficiently wet and/ or contain bog pool communities indicative of good condition.

### 4.4 Hydrology

- 4.4.1 A detailed hydrological catchment baseline survey for the study area based on field visits (CFJV, 2016 and 2017) and desk-based data assessments is presented in **Appendix 11.4 (Volume 2)**. This indicates that the study area drains to the River Spey. There are also several major and/ or minor watercourses present, the majority of which are direct tributaries of the River Spey; and **Chapter 11 (Volume 1)** identifies individual sub-catchments for each of these.
- 4.4.2 A network of artificial drainage channels of varying continuity and length also exist across parts of the study area, variably draining to existing watercourses and the points at which they cross the existing A9; as illustrated in **Drawings 10.5.8 (Volume 3)**. These are most frequent at the margins of existing or recent infrastructure and arable fields; and some are located in or adjacent to areas of peat. Where present, such artificial drainage will lower water table levels in and degrade areas of peat to make them more amenable for a particular purpose, but water has been observed at, or near, the surface in or nearby some areas; indicating local saturation as previously noted.
- 4.4.3 No sub-surface peat pipes were identified in the peat profiles during investigations, peat probing or other walkover surveys completed.

### 4.5 Peat Characteristics

- 4.5.1 The following sections present detail of the basic peaty soil and peat characteristics based on available depth and characteristic data, as presented in **Annex 10.1.2** and **Annex 10.1.3**.

### Peat Depth

- 4.5.2 The occurrences of peaty soils and peat correspond reasonably well with the ecology survey findings; with peaty soils and topsoil (less than 0.50m thickness) predominant in areas of dry or wet heath and mosaics of these and grassland transitions. These ranged from 0.05 to 0.50m in thickness and were generally described to vary from sandy, silty, clayey soil or topsoil that is variably peaty or contains pockets of peat with fibrous or pseudo-fibrous elements, but also occasional thin fibrous or pseudo-fibrous peat horizons. Discontinuous pockets of shallow peat (between 0.50 and 1.00m thickness) are present in similar areas locally, with some areas of deep peat (greater than 1.00m thickness) located in areas of wet heath, blanket bog, mosaics of these, other mires, fens, marshes and swamp.
- 4.5.3 The full range of recorded peat and peaty soil depths across areas investigated for the Proposed Scheme varied from 0.05 to 4.85m, as illustrated in **Drawing 10.11 to 10.22 (Volume 3)**. However as summarised in **Figure 1**, the vast majority of areas (around 77%) within the permanent and temporary works boundaries are underlain by peaty soil or topsoil less than 0.50m thickness, and around 11% is underlain by no peat. Shallow peat is present underlying less than 4% of the areas and less than 1% is underlain by deep peat. Available GI has also identified peat strata, between 0.10 and 3.30m thickness, buried beneath granular horizons of made ground and/ or sands and gravels at several locations.
- 4.5.4 Approximately 7% of the permanent and temporary works boundaries of the Proposed Scheme is without real or interpolated peat depth data. However, desk-based and ecological survey information indicate that peat greater than 0.50m is unlikely to be present in most of these areas as they are predominantly situated on superficial deposits of glaciofluvial origin.

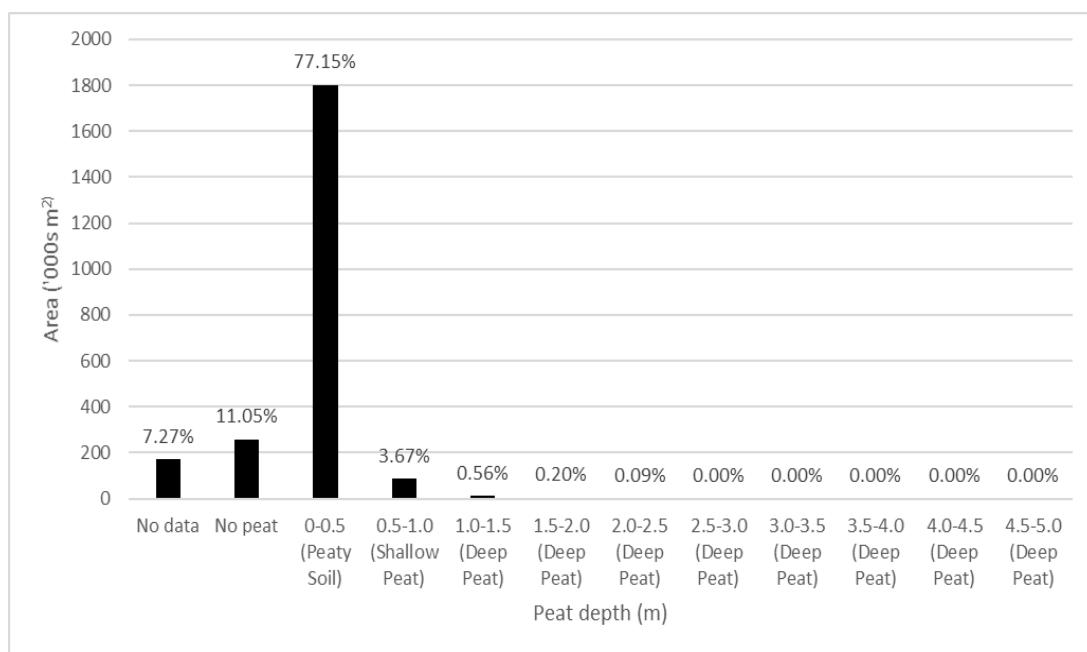

Figure 1: Peaty Soil and Peat Depth Distribution

### Acrotelm-Catotelm

- 4.5.5 The true depth of the acrotelm is often difficult to determine in the field and may be deeper than suggested by indicators such as living mosses and poorly decomposed plant material. Indeed, it has frequently been the case from investigation information available for the Proposed Scheme

that the acrotelm (i.e. that part of the peat profile which experiences fluctuations in water table) was recorded to be impacted or degraded.

- 4.5.6 In this respect, the acrotelm across the Proposed Scheme has been observed to predominantly comprise thin (0.05 to 0.30m) variably decomposed (H1 to H6, locally greater) layers and variably distinct semi-natural vegetation. The decomposition varied throughout, with several areas with decomposition ratings higher than would be expected for an acrotelm that is healthy and actively peat-forming. However, areas showing no or only very slight decomposition (H1 to H3) with distinct vegetation indicating good condition were also observed locally – around the proposed Newtonmore junction (ch. 42,700 to ch. 43,600) and an area of mire located at Nuide (ch. 46,000). In areas conducive to flooding, within the River Spey floodplain and Insh Marshes, high proportions of mineral content (sand, gravel and silt) were observed in the acrotelm layers.
- 4.5.7 The catotelm layers underlying the acrotelm were recorded to vary between spongy, plastic and firm condition. The type of peats also varied from dark brown and black fibrous to pseudo-fibrous, and locally amorphous; with highly variable root, wood, sand and silt content. Pseudo-fibrous peat was typically described as H3 to H7 on the von Post scale (very slight to strong decomposition), fibrous peat was typically described as H1 to H5 (no decomposition to moderate decomposition), while locally more amorphous peat or amorphous content within it was described as H8, H9 or H10 (very strong, nearly complete or complete decomposition).

#### Humification

- 4.5.8 **Figure 2** summarises the degrees of humification recorded on the von Post scale across the study area, versus the depths at which these were observed.

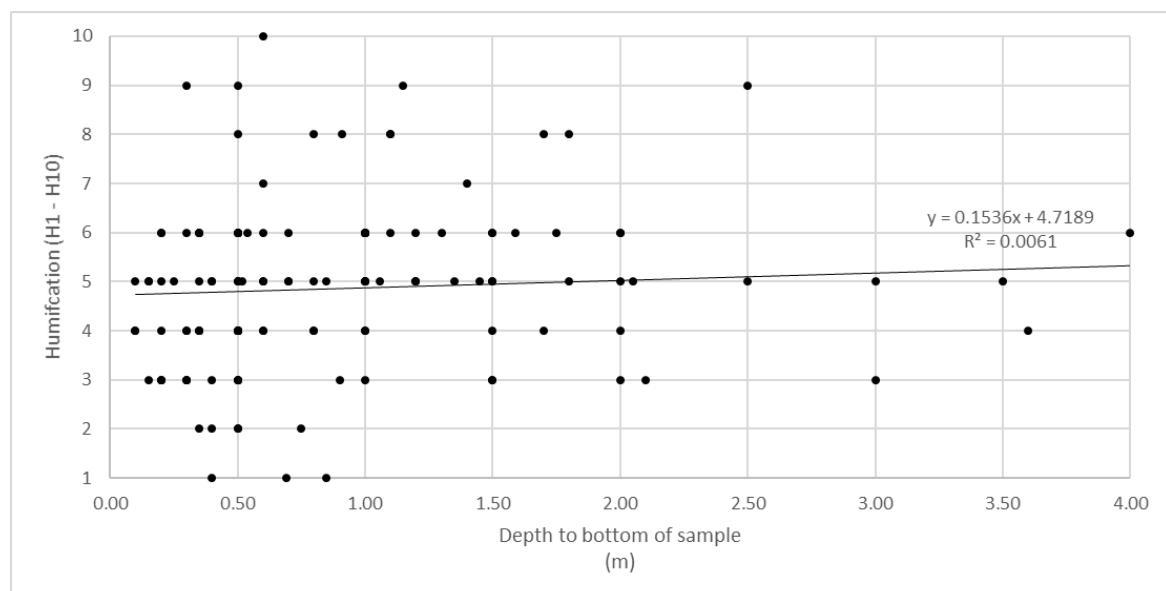

Figure 2: Degree of von Post Humification versus Sample Depth

- 4.5.9 Approximately 75% of samples obtained at less than 1.00m were described as H5 or less on the von Post scale, with 17% classified as H6 and 8% classified as H7 or greater. Samples from 1.00m or deeper recorded 75% of samples to be H5 or higher, and peat that was very strongly or completely decomposed (H8 or greater) was recorded at the base of the profile in some samples.
- 4.5.10 Overall, the results indicate that there is a very weak trend for humification to increase with depth due to the local instances of very strongly, nearly complete or completely humified (H8 or

greater) peat being found at shallow depths less than 0.50 or 1.00m. This may reflect the modified nature of the peatland environments in the vicinity of the Proposed Scheme.

#### Water Content

- 4.5.11 Estimated water contents of samples have covered the full range of possible values on the Von Post scale. **Figure 3** illustrates that there appears to be practically no correlation between water content and depth. This may reflect, at least in part, the timing of the sampling. Particularly at shallow depths, the water content will have been dependent on the antecedent conditions, such as during winter when the water table is likely to be seasonally higher.

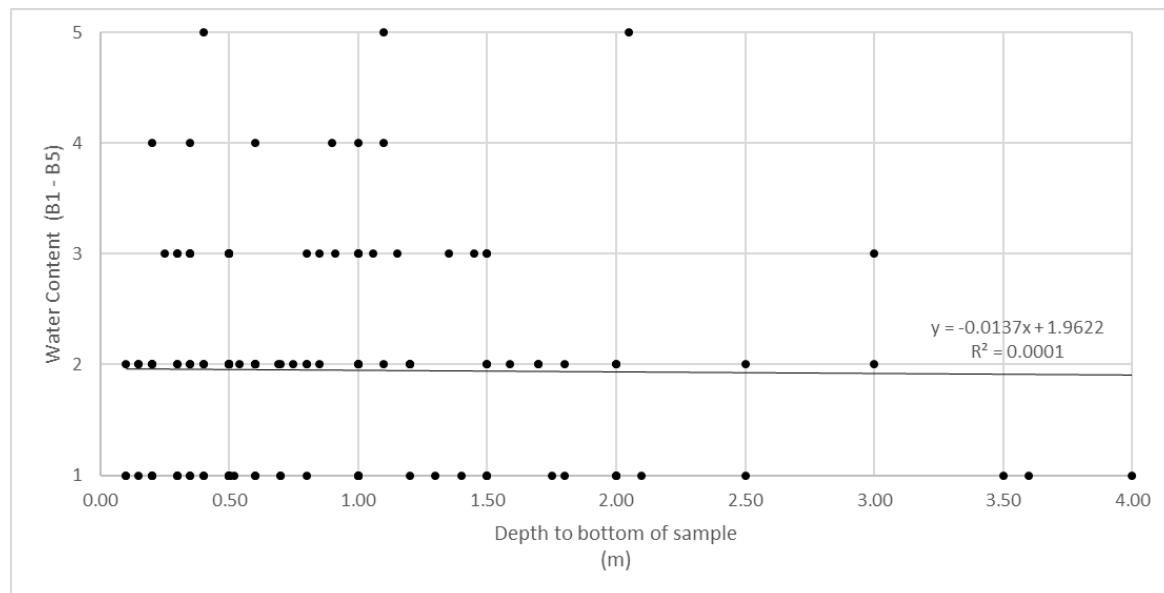

Figure 3: Estimated Water Contents versus Sample Depth

#### Fibrous Content

- 4.5.12 Low to moderate proportions of the coarse fibres (R0 to R2) of sphagnum mosses, herbaceous or woody plants were observed at shallow depths within younger parts of the peat profiles; the type being dependent on the surrounding habitat and vegetation. The proportions generally decreased to low or absent (R1 to R0) with depth; where low to moderate content of fine fibres (F1 to F3) of similar species were observed, albeit being less distinct as would be expected.

#### Wood Remnants

- 4.5.13 Some samples were observed to contain wood remnants, comprising between 25 and 75% of certain profiles. Those at shallower depth distinctly corresponded to more recent deposition of the roots and stumps of woody plants such as heather in areas of wet heath and blanket bog, with less distinct detrital fragments at greater depths.
- 4.5.14 The organic sediments within the peat were observed to variably be comprised of the humified roots, stem, rhizome or leave remains from sphagnum mosses, herbaceous or woody plants; the type being dependent on the surrounding habitat and vegetation as previously noted. These and

detrital fragments of the same variable made up 25% to 50% of the peat profiles and became less distinct with depth.

- 4.5.15 Intercalated mineral content within the peat profiles varied, but the highest proportions were generally observed in areas within the River Spey floodplain and Insh Marshes. Clay and sand were observed to frequently comprise between 25% and 75% of the components in several samples, with gravel and silt also noted at between 25% and 50% of certain profiles or as minor components less than this.

#### Substrate

- 4.5.16 The substrates underlying the peats within the study area are predominantly granular and were frequently difficult to penetrate and recover with the sampling equipment used. However, this corresponds well with published BGS mapping indications. Some trial pits, boreholes and peat coring locations also identified the presence of clay or silt substrate beneath the peats, but in all instances, these had notable amounts of sand as a secondary component and are therefore likely to be fine-grained tills.

#### Laboratory Testing

- 4.5.17 Laboratory testing of peaty soil and peat samples for all, or a selection of loss on ignition, moisture content, bulk density, pH, total carbon and total organic carbon from selected peat core locations was undertaken as part of the Preliminary GI. The results available across the profiles for each are presented in **Annex 10.1.3** together with vegetation/ habitat types at each sample location, and a summary is presented in **Table 3**.

*Table 1: Laboratory Testing Results*

Parameter	Peaty Soil/ Topsoil			Shallow Peat			Deep Peat		
	Min.	Max.	Mean	Min.	Max.	Mean	Min.	Max.	Mean
Bulk Density (Mg/m <sup>3</sup> )	0.07	0.29	0.21	0.33	0.49	0.41	0.14	0.58	0.39
Dry Density (Mg/m <sup>3</sup> )	0.02	0.05	0.03	0.03	0.09	0.06	0.02	0.22	0.06
Moisture Content (%)	98	1443	516.27	272	1423	624.33	98	1372	697.83
Loss on Ignition (%)	19	97	64.25	15	94	66.29	30	100	77.81
Total Carbon Content (%)	6.80	46.00	23.58	4.90	51.00	30.43	15.00	54.00	35.25
Total Organic Carbon (%)	5.50	44.00	21.78	5.40	43.00	27.49	11.00	55.00	33.33
pH (Units)	3.60	5.90	4.49	3.50	5.30	4.27	3.70	6.60	4.60

- 4.5.18 With the exception of two samples recorded at 42 and 46%, the results indicate that the vast majority of peaty soils and topsoils in the study area have a low or very low % carbon between 2 and 20%. Shallow peat profiles also exhibited low % carbon, with approximately 50% of the samples ranging between 5 and 33%. Deeper peats had generally higher ranges between 30 and 54%; but with lower % content in some samples from shallower parts of the profiles – likely to be indicative of degradation to these.
- 4.5.19 The results otherwise confirm some expected relationships and properties, such as the acidic and nutrient-poor nature of the soils and peats, with variable moisture content. However, the bulk dry density results for the shallow and deep peat samples is noted to be lower than ranges typically expected (Scottish Government, 2014; SEPA and James Hutton Institute, 2015).

## 5 Conclusions

- 5.1.1 Based on the baseline peat characteristics, geomorphology, habitats and hydrology; areas of peaty soils and peat within the study area are considered to be predominantly drained and/or modified in condition due to historical and recent development or land management activity. However, and although not pristine, some areas also appear to locally be in good condition, with a relatively intact hydrological regime and containing bog pool communities.
- 5.1.2 At a broad scale based on the criteria in **Table 10-1** within **Chapter 10 (Volume 1)** and SNH Carbon and Peatland mapping (SNH, 2016); the entirety of the Proposed Scheme extent would be considered negligible sensitivity in relation to peaty soils and peat – as there are no areas of priority peatland present. At a more local scale however, it is noted that this is contradicted by the occurrence of certain habitats and peat-forming vegetation types within the study area.
- 5.1.3 In this respect, the broader functions, values and core ecosystem services (including carbon storage) which these areas may provide are recognised based on those set out by the UK NEA (2011) and JNCC (2011) in **Table 2**; particularly in relation to the regulating, cultural and supporting services for blanket bog, wet heath, fen, marshes and swamp. The various habitats within the study area are also likely to be strongly influenced by the soils present (be it peaty soils, shallow or deep peat), with those habitats in turn either being important for local diversity, listed in Annex 1 of the European Council Habitats Directive 92/43/EEC (Council of the European Communities, 1992) and/ or being located within, adjacent to or nearby areas of environmental designation associated with the Insh Marshes.
- 5.1.4 All aspects taken together, the habitats and vegetation suggest that some areas of peaty soil and peat across the Proposed Scheme would be considered medium or high sensitivity, for one or more reasons. Such areas are reasonably indicated through the distribution of blanket bog, wet heath, mosaics of these, other mires, fen, marsh and swamp shown in **Drawings 12.8 to 12.27 (Volume 3)**; as these correspond to the areas of deepest peat and otherwise, areas of higher conservation value. The remaining areas of peaty soils mostly correspond to occasionally wet, but predominantly dry, acidic and more fragmented areas of dry heath, wet heath and grassland or open vegetation transition types. These don't represent priority peatland and are otherwise, areas of generally lower conservation interest which would be low or negligible sensitivity.
- 5.1.5 The key areas of medium and high sensitivity based on the information available are considered to include shallow and deep peat associated with wet heath and blanket bog within and adjacent to the proposed junction at Newtonmore (ch. 42,700 to ch. 43,600), an area of mire located at Nuide (ch. 46,000), a wet heath, blanket bog, mire and swamp complex south of the existing A9 at Cemetery Marsh (ch. 51,400 to ch. 52,200) and otherwise, the wider areas of fen, marsh and swamp associated within and throughout the River Spey – Insh Marshes Ramsar, Special Protection Area (SPA) and Site of Special Scientific Interest (SSSI) and the Insh Marshes Special Area of Conservation (SAC) and National Nature Reserve (NNR).

12 January 2018	PCBH170	277566	801764	230	0.60	Undertaken adjacent to borehole location to recover peat samples	W11d

Equipment	Mackintosh prospecting probe kit with 1.00m extension rods, Van Walt Russian Corer with 1.00m extension rods
GPS Equipment (Accuracy)	Garmin eTrex 12-channel GPS (+/- 3.00 to 7.00 m)
Staff/ Contractor	BAM Ritchies (on behalf of CH2M Fairhurst Joint Venture and Transport Scotland)

# Annex 10.1.3

## Peat Characteristic Data

Table 1: Advanced Ground Investigation (Raeburn, September to November 2015) (Boreholes and Trial Pits)

Location ID	Easting	Northing	Depth to Top (m)	Depth to Bottom (m)	Thickness (m)	Basic Peat/ Peaty Soil Description	Von Post Classification	Groundwater Level (m)
BH9-013	276659.0	801025.5	0.20	1.20	1.00	Dark brown slightly gravelly peaty fine to coarse SAND	-	1.00
BH9-014	277438.2	801721.8	0.10	2.00	1.90	Dark brown sandy fibrous PEAT with roots	H5, B1	2.50
BH9-017A	278620.8	802004.6	1.80	2.20	0.40	Brownish grey SAND and GRAVEL with pockets of dark brown PEAT	-	2.50
BH9-025	270669.5	796980.4	0.00	1.10	1.10	Dark brown fibrous PEAT with very high root content	H6, B2	1.10 / 10.00
BH9-025A	270669.0	796979.4	0.00	1.00	1.00	Dark brown fibrous PEAT with very high root content	H6, B2	1.00
BH9-026	270756.7	796942.5	0.00	0.20	0.20	Dark brown sandy gravelly peaty TOPSOIL with medium cobble content	-	14.30 / 20.50
BH9-029A	269747.6	796551.7	4.40	4.80	0.40	Dense dark brown fibrous PEAT with high root content	H3, B3	-
BH9-031	270751.2	797174.2	0.00	0.35	0.35	Dark brown fibrous PEAT with high root content	H4, B3	DRY
BH9-031A	270748.3	797172.6	0.00	0.35	0.35	Dark brown fibrous PEAT with high root content	H4, B3	4.60
BH9-034	276511.6	800572.7	0.00	0.50	0.50	Dark brown peaty TOPSOIL with rootlets	-	-
TP9-001	269108.3	794683.9	0.45	1.70	1.25	Dark brown fibrous locally plastic PEAT with roots, lenses of sand	H4, B2	DRY
TP9-002	269149.3	794879.6	0.00	0.30	0.30	Dark brown and black fibrous locally plastic slightly peat with roots, pockets of sand and gravel	H3, B1	2.20
TP9-004	269256.3	795363.4	0.00	0.10	0.10	Dark brown slightly pseudo-fibrous PEAT with low and medium root content	H4, B1	DRY
TP9-007	269369.5	795865.8	0.00	0.60	0.60	Dark brown slightly sandy pseudofibrous PEAT with roots and pockets of gravel	H4, B1	DRY
TP9-009	269566.0	796208.7	0.00	1.10	1.10	Greyish brown sand with roots, and pockets of dark brown pseudofibrous PEAT (possible landslip)	-	DRY

## Peat Depth Model Methodology

### Peat Depth Model Methodology

The peat depth model has been generated using ArcGIS 10.3.1 geographical information system (GIS) software, a widely available, industry standard software package. ArcGIS provide several different methods of interpolating a surface with varying values (in this case peat depths) across an area from real, measured data points.

The method used to create the peat depth model for this project has involved creating a Triangular Irregular Network (TIN) which connects real measured data points via a series of edges to form a network of triangles (ESRI, 2016). The TIN is subsequently converted from a TIN into a ‘Raster’ (i.e. a grid of cells of equal dimensions bases on a specified resolution, such as 1m by 1m) to allow further analysis (RWE, 2013a)).

This method has been chosen following detailed analysis at the Carnedd Wen Wind Farm site in Mid-Wales, which showed that, of the various methods available in ArcGIS, the TIN to raster method was preferable due to:

- Its mathematical simplicity
- The reduced likelihood of it reducing the size of, or ‘smoothing out’ completely, smaller areas of deeper peat
- It being true to the measured dataset from which it is created, in that the value of the peat model surface at a measured data point will always be equivalent to the value at that data point (RWE, 2013a).

Additionally, work at Carnedd Wen found there to be little discernible impact on the model between specified raster resolutions of 5m, 10m and 20m. At Carnedd Wen, a raster resolution of 5m was used so that the peat depth can be more accurately represented where data points are closely spaced, such as at known proposed infrastructure locations.

For the peat model created for the Proposed Scheme, a resolution of 1m has been used. It is acknowledged that such a resolute raster may ‘over-represent’ the resolution of the survey, i.e. give an impression that more data has been collected than is actually the case. However, by using such a resolution, sudden step changes in peat depth (where none is present in reality) are avoided, calculations of volumes are more straightforward as each raster grid cell represents a 1m<sup>2</sup> area (rather than a 25m<sup>3</sup> area) and inaccuracy in volume calculation caused when the footprint of infrastructure elements overlaps partially with a grid cell.

At the Carnedd Wen site, ‘barriers’ were introduced to the model to reduce the peat depth to zero where streams were known to be incised to substrate, and where lakes and streams existed. Such barriers have not been employed for the Proposed Scheme here, as this technique was resulting in areas being interpolated as zero peat depth, where this might not be the case. Instead, any such features including watercourses incised to substrate, existing road or tracks where no peat is present, have been ‘reduced to zero’ from the peat model. Embankments and cutting slopes have deliberately not been ‘reduced to zero’ peat depth to account for the possibility that dressing of these slopes has been undertaken with peat or peaty soil.

### Peat Depth Model Iterations and Testing

Numerous peat model iterations have been produced as new data has been acquired at various stages of survey. Whilst no specific testing has been undertaken to verify the accuracy of the peat model using ‘redundant’ points, where new data has been collected in

areas where peat depth has been interpolated the change has usually been marginal and the new data has broadly confirmed rather than contradicted interpolated peat depths. Nonetheless, as new data becomes available, the model should be updated to ensure the highest accuracy possible.
